We report on a detailed investigation of exclusive J/ψ production in proton–proton and proton–antiproton collisions. Predictions for Tevatron and LHC energies are included.

Keywords: Diffraction; Exclusive Processes; Heavy Quarks.

PACS numbers: 13.87.Ce, 13.60.Le, 13.85.Lg

1. Introduction

Diffractive production of vector mesons has been a major subject at HERA, and the large body of data obtained serves to elucidate the physics of the QCD–Pomeron and/or the small–x gluon density in the proton [1]. For a review at this workshop, see [2]. While data–taking at HERA has come to an end, hadron colliders, such as Tevatron and LHC provide opportunities to study photoproduction processes at still higher energies than those covered by HERA. The exciting experimental possibilities at Tevatron at LHC have been presented at this workshop in the plenary talk [3]. Besides the photoproduction mechanism of exclusive J/ψ–production in hadronic collisions, there could also exist a purely hadronic mechanism, where the J/ψ production proceeds through the Pomeron–Odderon fusion. From this point of view a detailed study of the photoproduction mechanism, if possible including the effects of absorptive corrections is much desired. The results presented here are based on ref. [4] and ongoing work with A. Rybarska. For an analogous study of Υ production, see [5].

2. Results and Conclusions

The mechanism for exclusive J/ψ production is depicted in fig.(1). The exchanged photons have small virtualities, certainly $Q^2 \ll m^2_{J/\psi}$, and what enters the calculation is the photoproduction amplitude $\gamma p \to J/\psi p$. Under mild assumptions, this subprocess amplitude can be directly obtained from the HERA data on t–

distributions of J/ψ's,

$$\mathcal{M}(\gamma p \to J/\psi p; s, t) \propto (i+\rho)\sqrt{d\sigma(s)/dt|_{t=0}}\,\exp(Bt/2)\,. \tag{1}$$

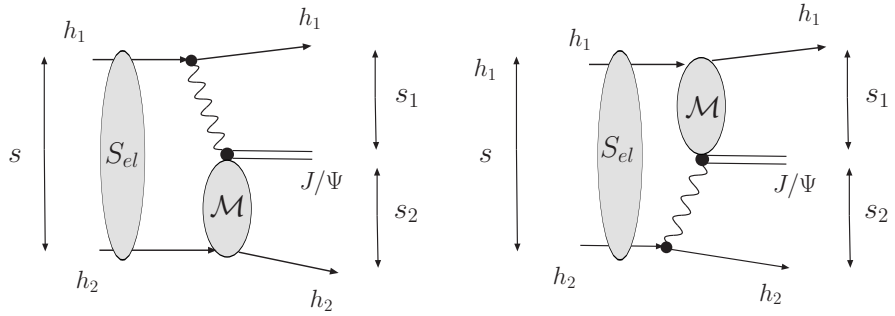

Fig. 1. A diagrammatic representation of the exclusive J/ψ–production mechanism in hadron–hadron scattering. Here the blob labeled $\mathcal{M}$ corresponds to the photoproduction amplitude of J/ψ on hadron $h_{1,2}$. The blob S_{el} stands for the absorptive correction. Some kinematic variables are indicated.

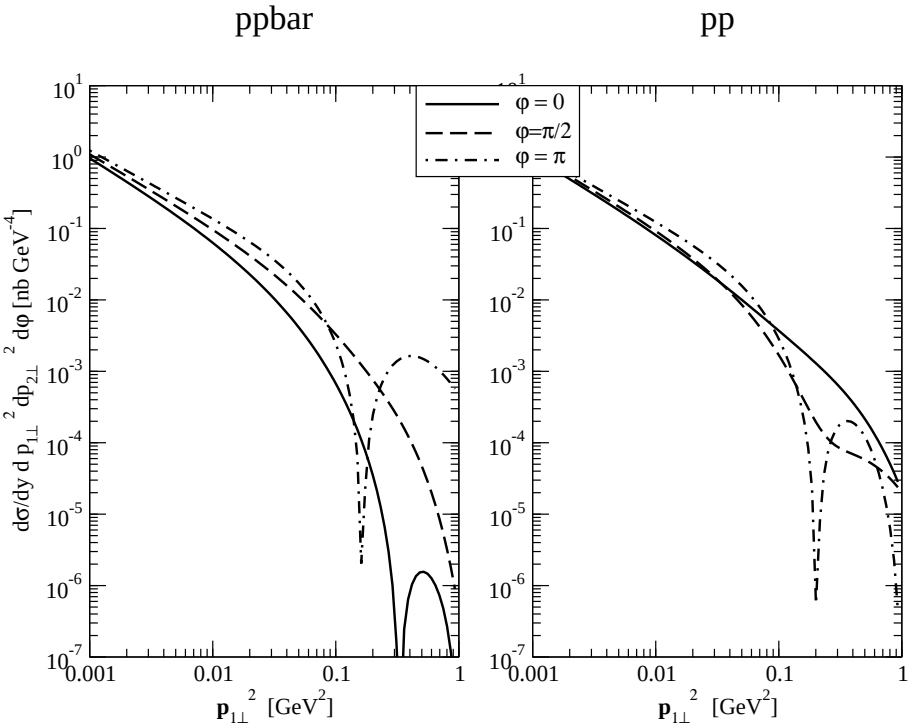

Fig. 2. **Left**: Fully differential cross section as a function of $\mathbf{p}_1^2$ at $y = 0$ and $\mathbf{p}_2^2 = 1$ GeV^2 for $p\bar{p}$ collisions at $W = 1960$ GeV. **Right**: the same for pp collisions.

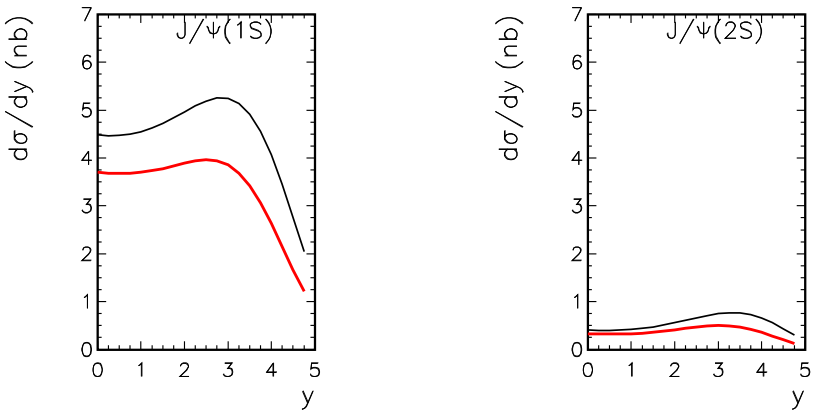

Fig. 3. **Left**: $d\sigma/dy$ at $W = 1960$ GeV for J/ψ–production. The upper curve is without absorptive corrections, while the lower curve includes them. **Right**: the same for $\psi'(2S)$.

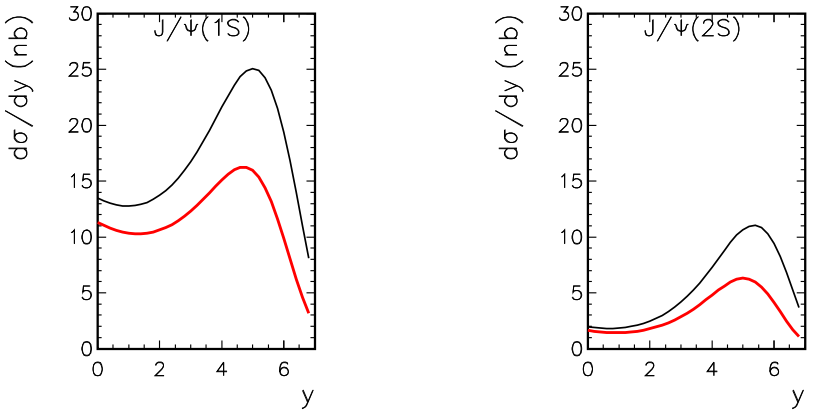

Fig. 4. **Left**: $d\sigma/dy$ at $W = 14$ TeV for J/ψ–production. The upper curve is without absorptive corrections, while the lower curve includes them. **Right**: the same for $\psi'(2S)$.

In particular, we assumed that s–channel helicity conserving pieces dominate, which is indeed borne out by experiment, see the detailed review [1] for references. The second ingredient is the amplitude for elastic scattering of the incoming (anti–)protons, which enters in the evaluation of absorptive/rescattering corrections. We also essentially take it from data. Our resulting predictions are then only mildly model–dependent. Some reservations exist regarding the possible presence of inelastic intermediate states in the rescattering diagram, which can however be estimated by simple enhancement factors. From the large amount of detailed plots shown in our presentation we select a few representative ones: In fig(2), we show a scan of the

fully differential cross section $d\sigma/dyd\mathbf{p}_1^2 d\mathbf{p}_2^2 d\phi$, at Tevatron energies. Here y is the rapidity of the J/ψ, $\mathbf{p}_{1,2}$ are the transverse momenta of the outgoing (anti–)protons, and ϕ is the azimuthal angle between them. The dependence on ϕ is caused by the interference of the two diagrams of fig(1), which enters with a different sign in pp and $p\bar{p}$ collisions. The steep peak at small $\mathbf{p}_1^2$ is naturally due to the photon pole. The rich dip–bump structure is fairly sensitive to the precise treatment of absorptive corrections, for more details, see [4]. The plots of figs(3, 4) are results not contained in [4]. Here, for the $\gamma p \to J/\psi p$ subprocess we did not use a purely phenomenological parametrisation, but used a pQCD–based $k_\perp$–factorisation approach [1] to calculate the relevant amplitude in terms of an unintegrated gluon density of the proton and the light–cone wave function of the final state vector meson. This machinery allows us to calculate also production of excited vector mesons, for which HERA data are rather sparse and insufficient for predictions directly from data. In fig(3) we show the rapidity spectra $d\sigma/dy$ at Tevatron energies. In the left panel we show results for the $J/\psi(1S)$, in the right panel we display the cross section for production of the radial excitation $\psi'(2S)$. Here, the light cone wave functions of $J/\psi, \psi'(2S)$ which we used are purely phenomenological ansätze, constrained by the decay width to leptons, as well as the orthogonality condition [1]. We checked, that our form of the wavefunction leads to a good description of the $\psi'/J/\psi$–ratio measured in photoproduction at HERA. The size of the ψ' production cross section roughly corresponds to the $\psi'/J/\psi$–ratio in photoproduction. In fig(4) we show predictions for LHC–energies. An accurate treatment of absorption at LHC energies must go beyond the elastic rescattering included so far, still our estimates of fig(4) could be of some use. The rise of the y–distribution from central rapidities to the peak reflects the Pomeron intercept in the $\gamma p \to J/\psi p$ production amplitude, and could be further affected by absorptive corrections to that subprocess. Already the included absorptive corrections affect the shape of the rapidity distribution, because larger y also involves larger photon virtualities, and hence shorter distances, where absorption is stronger. While analysis is in progress at the Tevatron [3], measurements of exclusive J/ψ at LHC will be very challenging, prospects are better for Υ's discussed in [5].

Acknowledgments

It is a pleasure to thank Jim Pinfold for discussions during MESON2008. This work was partially supported by the Polish Ministry of Science and Higher Education (MNiSW) under contract 1916/B/H03/2008/34.
